## ABSTRACT OF THE DISCLOSURE

A filter coefficient of a graphic equalizer GEQ is corrected based on detection results of reproduced sounds generated by supplying a noise to all frequency band loudspeakers  $\theta_{\text{FL}}$  to  $\theta_{\text{RR}}$  and a low frequency band exclusively reproducing loudspeaker  $6_{\text{WF}}$  via the graphic equalizer GEQ. Then, attenuation factors of channel-to-channel attenuators ATG1 to ATG5 are corrected based on the detection results of the reproduced sounds generated by supplying the noise to the loudspeakers  $6_{\text{FL}}$  to  $6_{\text{RR}}$  via the graphic equalizer. Then, delay times of delay circuits  $DLY_1$  to  $DLY_k$  are corrected based on the detection results of the reproduced sounds generated by supplying the noise to the loudspeakers  $\theta_{\mathtt{FL}}$  to  $\theta_{\mathtt{WF}}$  via the graphic equalizer. Then, an attenuation factor of a channel-tochannel attenuator  $\mathtt{ATG}_k$  is corrected based on the detection results of the reproduced sounds generated by supplying the noise to the loudspeakers  $6_{FL}$  to  $6_{RR}$  via the graphic equalizer and the detection result of the reproduced sound generated by supplying the noise to the loudspeaker  $6_{w_F}$  via the graphic equalizer, whereby levels of the reproduced sounds reproduced by the loudspeakers  $6_{\text{FL}}$  to  $6_{\text{WF}}$  are adjusted to be made flat over the audio frequency band.
